Linking local production impacts with consumption

Implementation for Assessment of Impact on Drivers of Biodiversity Loss

Elena Dawkins, Chris West, Simon Croft

elena.dawkins@york.ac.uk

Presentation Overview

- 1. Project Background
- 2. Approach to the Project
- 3. Methods applied
- 4. Results extract
- 5. Discussion (limitations, extensions)

Project Background

- Project Duration: Nov 2011 April 2013
- Funder: Department for Environment Food and Rural Affairs, UK
- The Issue
 - Growing consumption, continued reliance on imports
 - Complex supply chains
 - Indirect and direct impacts of consumption
 - Overseas biodiversity impacts
- Project Aim
 - provide a database-driven methodology for linking UK imports to geographically-defined impacts on biodiversity

Policy Drivers

- Convention on Biodiversity Diversity (CBD) 1992
- Most recent targets for signatories are Aichi
- Aichi target 4 states:
 - "By 2020, at the latest, Governments, business and stakeholders at all levels have taken steps to achieve or have implemented plans for sustainable production and consumption and have kept the impacts of use of natural resources well within safe ecological limits"
- Defra want to find ways to measure and monitor this, this project contributes to research. We focus on the sustainable consumption

Approach to Classify and Prioritise Impacts

- Standard trade data do not capture indirect impacts of consumption via supply chains
- Full consumption assessment requires supply chain data
- Need to identify the location of production to assess local impacts
- Focus on drivers of biodiversity loss from production activities, rather than trying to quantify the impacts on individual species

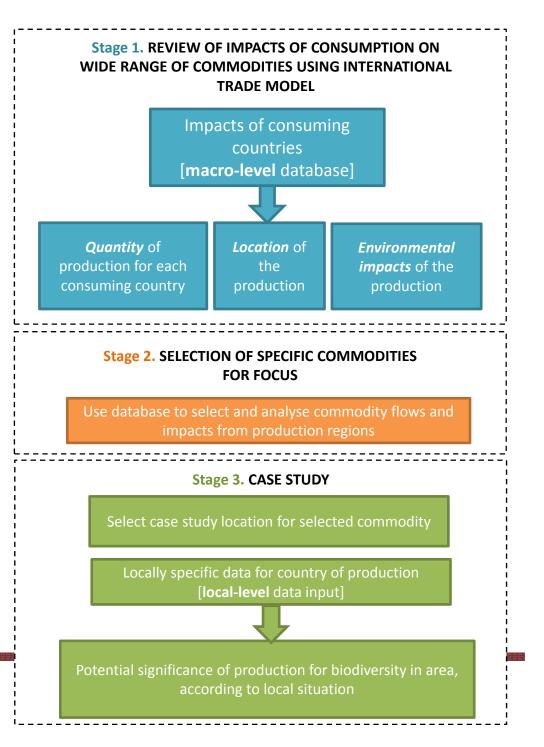

WP1: Existing Studies

Approach

- Assessment framework developed
- Specific method/ approach developed for each stage

Methods Applied

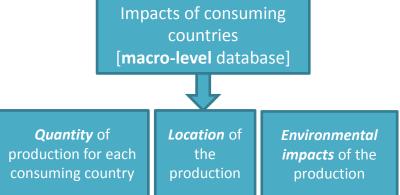

Stage 1

Create a database of consumption-based impacts for a range of commodities

- Consumption-based indicators (e.g. land/carbon footprint) exist, but with the following issues:
 - No data on local significance; need to link to local impacts
 - Usually at aggregated product-group level (e.g. footprint of dairy products)
 - Origin of production is not kept in database; difficult to trace
 - Reliance on financial data to track flows

1. REVIEW OF IMPACTS OF CONSUMPTION
ON WIDE RANGE OF COMMODITIES USING
INTERNATIONAL TRADE MODEL

Stage 1

Creating the consumption-based database

Apply common footprint method based on input-output analysis, but develop and adapt database to specific project needs (local-level production, physical data, product level detail...)

Techniques Applied:

- Multi-regional input-output (MRIO) model developed using GTAP8 data, following method described in Peters, G.P., Andrew, R., & Lennox, J. (2011)
- FAO physical data linked to MRIO model using methods described in Ewing et al. (2012) and building on the EUREAPA approach (<u>www.eureapa.net</u>)

Stage 1 Data Inputs

To track direct and indirect flows through global economy:

 GTAP8 database of financial trade flow data, between 129 countries/world regions and 57 sectors

To identify quantity and location of production in physical units:

- FAO database on production, imports and exports of up to 200 agricultural (fisheries/forest) commodities
- British Geological Survey and UN Comtrade for minerals production

To identify environmental impacts:

- FAOStat for land areas
- Water Footprint Network
- FertiStat
- Biodiversity databases (IUCN, WWF)

Stage 1 Data Outputs

- For Defra all data were organised according to the requirement to satisfy UK demand for all goods and services
- Once the database was complete we can view:
 - How many tonnes of commodity are required in each country to satisfy UK demand* for 57 goods/services
 - Estimated land (ha) and water (m3) is required to produce these tonnes
 - Then additional environmental information about that country

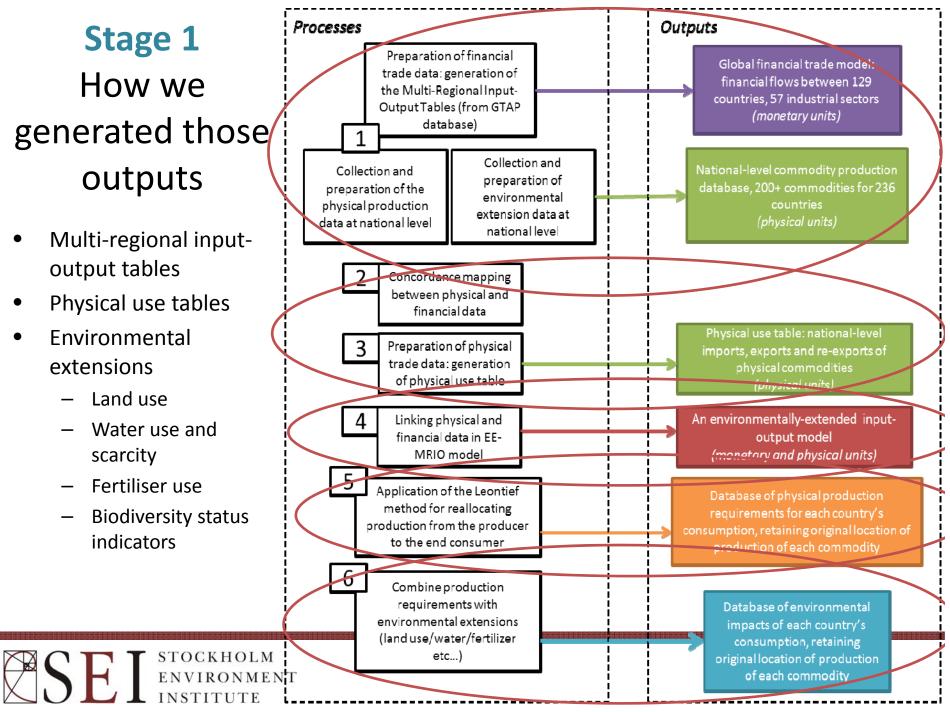

^{*} Run for UK for Defra, but 129 countries in the model

Stage 1

How we generated those outputs

- Multi-regional inputoutput tables
- Physical use tables
- **Environmental** extensions
 - Land use
 - Water use and scarcity
 - Fertiliser use
 - Biodiversity status indicators

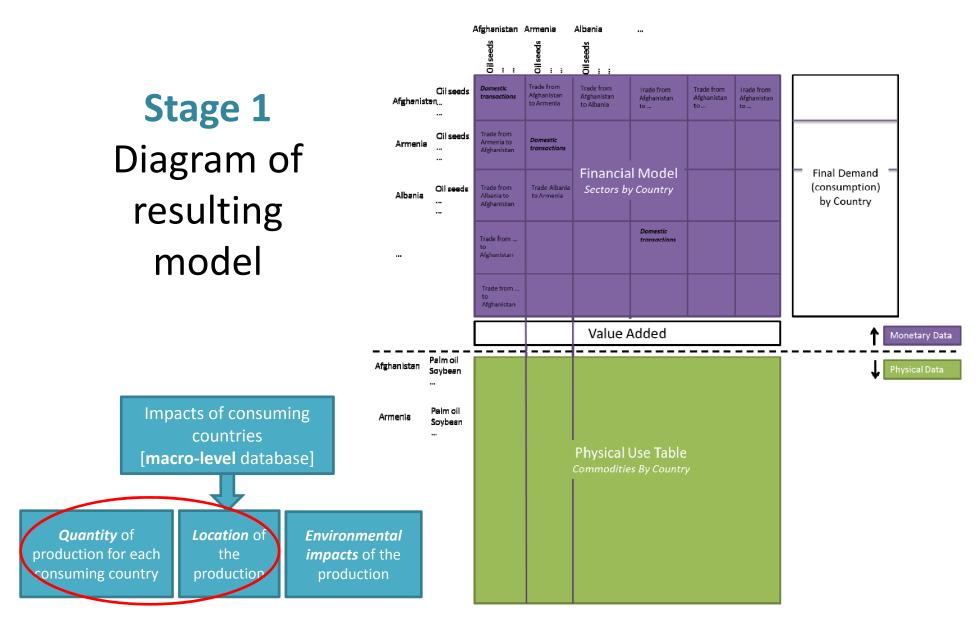

Diagram Adapted from: Brad R. Ewing, Troy R. Hawkins, Thomas O. Wiedmann, Alessandro Galli, A. Ertug Ercin, Jan Weinzettel, Kjartan Steen-Olsen, Integrating ecological and water footprint accounting in a multi-regional input—output framework, Ecological Indicators, Volume 23, December 2012, http://www.sciencedirect.com/science/article/pii/S1470160X12000714

Stage 1 Methods for Linking the Monetary and Physical Data

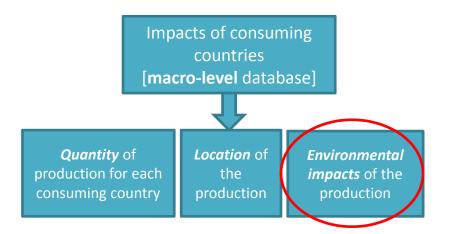

- Method 1: Allocate physical production of each product and country within FAO to an equivalent producing sector and region within GTAP
 - Relies solely on financial MRIO data to model trade in commodities between sectors
- Method 2: Allocate physical production to importing regions in GTAP using FAO trade data
 - Full 'MRIO-physical use' approach (Ewing et al. 2012); requires harmonisation of datasets and method for dealing with re-exports in the physical data
- Method 3: Create full physical input-output table
 - Retains product detail to greatest extent, but resource intensive and data often unavailable

Implementation Issues

- Dealing with region irregularities in FAO
- Data irregularities (e.g. unspecified trade) in FAO
- Import/export matching errors in FAO
- Re-exports algorithms developed
- Concordances between FAO and GTAP
- Other physical datasets Minerals and Fisheries

Stage 1 Environmental extensions added

Land area

 FAOStat contains yield data for each crop at national level that is multiplied by units of production.

Water use and scarcity

- Obtained from Water Footprint Network
- Green, blue and grey water use for each crop at national level that is multiplied by units of production
- Water scarcity available for major river basins; we transformed this into estimates of 'extreme' water scarcity at national level for comparison against blue water use outputs.

Environmental extension details continued...

Fertiliser application

- FAO Fertistat contains N,P, and K application data from some crops (and crop groups) and countries.
- Can be multiplied by area of production to obtain figures for consumption.
- Data is sparse and relatively old.

Biodiversity data

- IUCN Red List, Important Bird Area and WWF Global 200 regions are all associated with threats.
- KBAs and AZEs contain no threat data.
- Can be output at national level for comparison with other extensions.

Stage 2 Selection of Specific Commodities for Focus

2. SELECTION OF SPECIFIC COMMODITIES FOR FOCUS

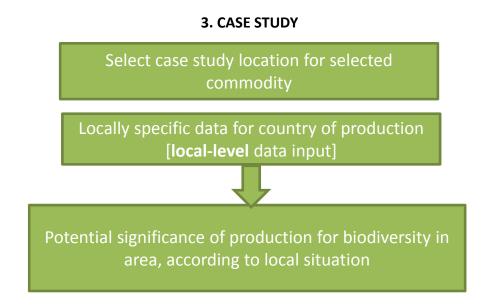

Use database to select and analyse commodity flows and impacts from production regions

- Steering group selected priority commodities for analysis and presentation in report:
 - bananas, bauxite, coffee, cocoa, cotton, hardwood (non-coniferous industrial roundwood), oil palm fruit (palm oil), rice, shrimp, soyabean, sugarcane and wheat

Stage 3

Selection of Commodity Location for In-Depth Case Study of Production System

 Brazil was selected as location for focus for soyabean case study and assessment of potential biodiversity impacts

Initial Results

- Model runs have been done for UK in detail and in summary for all of Europe (27 countries individually and aggregated) so far
- Limited time for detailed analysis
- Case studies completed for Soyabean in Brazil, Palm Oil in Indonesia and Malaysia. Some initial sugarcane case studies completed as well.

In which countries is the soyabean production for UK consumption of goods and services located?

What are the environmental impacts of the soyabean production for UK consumption?

Stage 3: Case Study Results

- Full case study provided in final report, some highlights:
 - 75% of soyabean grown in cerrado region of Brazil
 - Cerrado is large savannah-forest in northern Brazil and biodiversity hotspot (Conservation International)
 - Agriculture is main threat
 - Two-thirds of the cerrado has already been converted to agriculture (Galford, 2010)
 - Increasingly mechanised and concentrated production, larger plantations in North
 - Deforestation has slowed recently; concern that it may increase again
 - Other threats: soil erosion, chemical pollution, crop modification
 - Other issues: national policies, social and economic benefits

Limitations and Assumptions

- Data quality
 - Time lag
 - Aggregations
- Modelling assumptions
 - Sectoral imports assumptions
 - Physical trade assumptions
- Data availability
 - Limited trade data for some commodities (fish/minerals)
 - Limited data for some environmental extensions
- Interpretation
 - Very disaggregated, not aggregated into single footprint measure. Gives more detail but harder to assess.

Discussions, Limitations and Recommendations

- Framework helps to identify some possible local impacts of goods finally consumed in the UK
- Assesses a variety of different commodities in a consistent, comparable and repeatable manner
- Supply chain analysis demonstrates importance of considering all goods and services (e.g. soyabean embedded in wearing apparel example)
- Retention of country of production allows local-level assessment, important when local situation varies (e.g. water)

Next Steps

- Further analysis of results just database developed so far
- They would like to discuss an indicator...
- We have made a start on an application of structural path analysis method for EU analysis, early stages
- Use and testing of alternative datasets
- Downscale physical table to regions within Brazil using local-level production, trade and environmental data

Thank you!
