Abstract

The generalized Trivers-Willard hypothesis proposes that parents who possess any heritable trait

Follow up study surveyed 3000 Americans to test correlation between parents attractiveness sex of children.

56% of the children of parents in the highest attractiveness category were girls, compared to 48% of the children of parents in the other categories. Difference of 8% (standard error 3%)

- Gertler (2013) “Labor returns to Childhood stimulation”
- Randomized stimulation to stunted Jamaican toddlers living in poverty

- Gertler (2013) “Labor returns to Childhood stimulation”
- Randomized stimulation to stunted Jamaican toddlers living in poverty
- One-hour weekly visits from community Jamaican health workers over a 2-year period. Earnings measured 20 years later (n = 127)

- Gertler (2013) “Labor returns to Childhood stimulation”
- Randomized stimulation to stunted Jamaican toddlers living in poverty
- One-hour weekly visits from community Jamaican health workers over a 2-year period. Earnings measured 20 years later (n = 127)
- Estimated increase in earnings 42%, Confidence interval [2%, 98%]

- Gertler (2013) “Labor returns to Childhood stimulation”
- Randomized stimulation to stunted Jamaican toddlers living in poverty
- One-hour weekly visits from community Jamaican health workers over a 2-year period. Earnings measured 20 years later (n = 127)
- Estimated increase in earnings 42%, Confidence interval [2%, 98%]

“We report substantial effects on the earnings of participants in a randomized intervention conducted in 1986–1987 that gave psychosocial stimulation to growth-stunted Jamaican toddlers. . . . the intervention had a large and statistically significant effect on earnings. . . . The estimated impacts are substantially larger than the impacts reported for the US–based interventions, suggesting that ECD interventions may be an especially effective strategy for improving long-term outcomes of disadvantaged children in developing countries.”

Effect estimation - 42% CI [2%, 98%] (N=127, std error \approx 0.12)

Suppose that the real effect on earnings is 10%

- What is the probability that we get significant results?

Effect estimation - 42% CI [2%, 98%] (N=127, std error ≈ 0.12)

Suppose that the real effect on earnings is 10%

- What is the probability that we get significant results?

significant?	n	exp.mn
FALSE	892	1.07
TRUE	108	1.52

Effect estimation - 42% CI [2%, 98%] (N=127)

Figure 1: *Bias in expected magnitude of effect size estimate, conditional on statistical significance, as a function of actual effect size, for the early-childhood intervention study of Gertler et al. (2014). The raw estimate, before selection is assumed to be normally distributed with mean equal to the true effect and standard error 0.12.*

Bayesians: “Update your belief!”

- 1 Prior belief
- 2 Data
- 3 Updated belief

Bayesians: “Update your belief!”

1 Prior belief $\sim N(0, 0.10)$

2 Data 1.42 CI [1.02, 1.98]

3 Updated belief: **prior + data**

Bayesians: “Update your belief!”

1 Prior belief $\sim N(0, 0.10)$

2 Data 1.42 CI [1.02, 1.98]

3 Updated belief:

1.09 CI [0.92, 1.28]

“Let the data speak..”
Effect estimation:
42% CI [2%, 98%]

“Update your belief.”
Posterior effect
9% CI [-8%, 28%]

$$y = 1 + 0.1 \cdot x + \text{error}$$

Estimating the slope

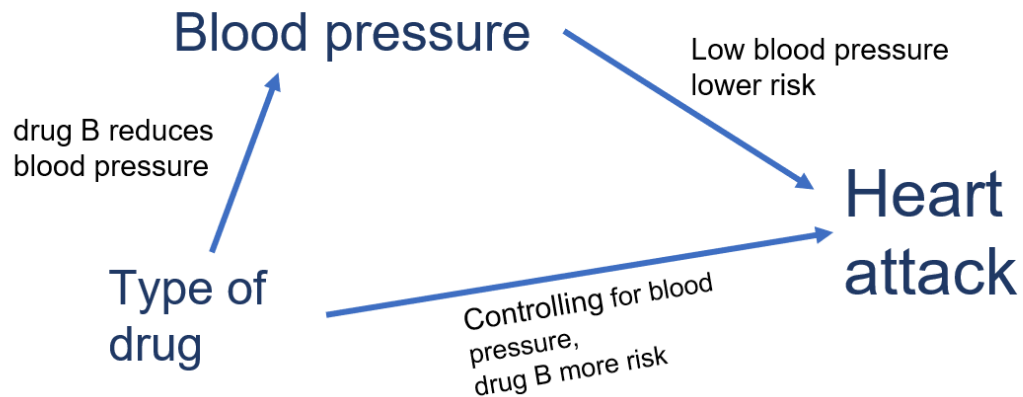

Frequentist (red) vs Bayesian (black)

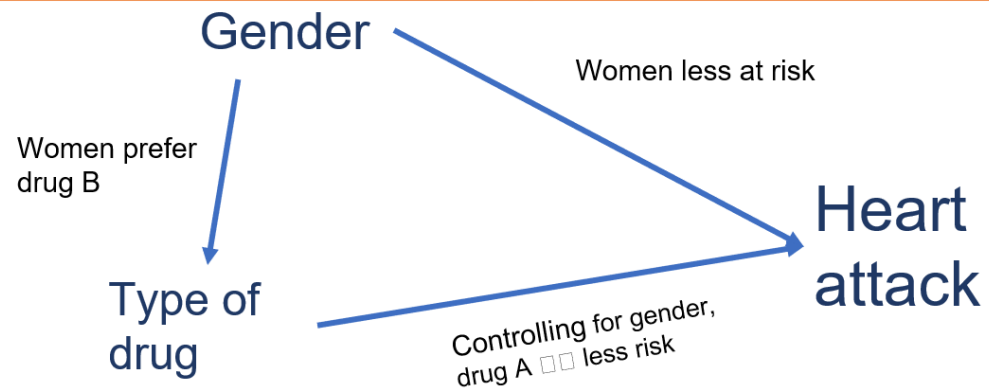

$$y = 1 + 0.1 \cdot x + \text{error}$$

error $\sim N(0, 0.5)$

	Drug A			Drug B		
	Heart attack	No heart attack	% of patients with heart attacks	Heart attack	No heart attack	% of patients with heart attacks
Low blood pressure	1	19	5.0%	3	37	7.5%
